

pointers

Yes. Based on the work we've covered so far, you have substantial hands-on DevOps experience across AWS infrastructure, Terraform, CI/CD, security, networking, databases, observability, and production deployment.

For a resume, I would avoid listing every individual console action. It will read stronger if we convert the work into **impact-oriented experience bullets**.

DevOps Engineer — AcordAI

- Designed, deployed, and maintained **AWS infrastructure across separate Development and Production environments** in Canada Central (`ca-central-1`), following environment isolation and production high-availability practices.
- Built modular **Infrastructure as Code using Terraform**, managing VPC, subnets, NAT Gateway, routing, security groups, ECR, ECS, ALB, RDS, ElastiCache, bastion infrastructure, IAM, S3, Secrets Manager, Route 53, and related AWS resources.
- Implemented **remote Terraform state management using Amazon S3**, maintaining separate state files and configurations for development and production infrastructure.
- Designed AWS networking with **public, private application, and database subnets**, Internet Gateway, NAT Gateway, route tables, security groups, and private database connectivity.
- Deployed containerized backend applications using **Amazon ECS Fargate**, including task definitions, ECS services, CPU/memory configuration, health checks, logging, environment configuration, and deployment troubleshooting.
- Configured **Amazon ECR** private repositories and integrated container image build/push workflows with ECS deployments.
- Configured an **Application Load Balancer** with HTTPS listeners, HTTP-to-HTTPS redirects, target groups, path-based routing, health checks, sticky sessions, and application-specific idle timeout tuning.
- Built **GitHub Actions CI/CD pipelines** for frontend and backend applications, automating validation, Docker builds, ECR image publishing, ECS deployments, and development environment releases.
- Implemented **GitHub OIDC authentication with AWS IAM**, enabling GitHub Actions to obtain short-lived AWS credentials instead of maintaining long-lived AWS access keys.
- Established a Git branching and release strategy using **feature branches, protected dev and main branches, pull requests, required CI checks, code freezes, and controlled production promotions**.

- Managed production releases using **squash merging and controlled dev → main promotion**, keeping production branch history clean and limiting continuous direct production deployments.
- Integrated **Gitleaks secret scanning** into frontend and backend CI pipelines and introduced pre-commit secret detection practices to prevent credentials and API keys from entering Git history.
- Managed application secrets through **AWS Secrets Manager**, including ECS secret injection and IAM permissions for task execution and application roles.
- Provisioned and administered **Amazon RDS PostgreSQL** environments, including private networking, encryption at rest, Secrets Manager-managed credentials, automated backups, maintenance windows, deletion protection, storage autoscaling, and parameter configuration.
- Designed the production PostgreSQL database for **Multi-AZ high availability**, understanding automatic failover, endpoint behavior, backups, snapshots, and point-in-time recovery procedures.
- Configured and validated **PostgreSQL SSL/TLS enforcement** through RDS parameter groups and secure application-to-database connectivity.
- Implemented an **SSM-based bastion host** without inbound SSH exposure and used Session Manager port forwarding for secure access to private PostgreSQL databases.
- Provisioned and evaluated **Amazon ElastiCache for Redis**, including encryption at rest/in transit, subnet placement, parameter groups, and production HA considerations.
- Integrated AWS infrastructure permissions for **Amazon Textract**, including S3 document storage, ECS task IAM permissions, and troubleshooting IAM `AccessDenied` issues.
- Configured **AWS Amplify Hosting for Next.js**, integrating GitHub branches with automated frontend builds and deployments for development and production.
- Managed custom application domains including **acordai.io and acordai.ai**, configuring Route 53 hosted zones, DNS records, ACM certificates, SSL validation, Amplify domain mappings, and API subdomains.
- Planned and executed **DNS migration from GoDaddy to Amazon Route 53**, preserving Microsoft 365 MX, SPF, DKIM, autodiscover, verification, and other existing DNS records to minimize service disruption.
- Troubleshoot application and infrastructure issues using **CloudWatch Logs, ECS service events, ALB target health/response metrics, RDS monitoring, browser network traces, and AWS CLI**.
- Diagnosed production-style application performance issues involving **synchronous workloads inside asynchronous APIs, single Uvicorn workers, ECS task concurrency, memory utilization, and ALB request handling**.
- Contributed to the design of an asynchronous processing architecture using **API → Amazon SQS → ECS worker services → RDS/S3**, allowing long-running policy/document

processing to be separated from request-serving API containers.

- Investigated and resolved frontend/backend routing issues including **HTTP 413 large-upload failures caused by Next.js proxying**, moving frontend requests to the backend API endpoint directly where appropriate.
- Performed AWS **cost analysis and optimization**, identifying major cost drivers including NAT Gateway, ALB, Fargate, RDS Multi-AZ, Redis, CloudWatch, public IPv4, and storage, and developed development-vs-production optimization strategies.
- Prepared infrastructure capacity and budget estimates for production, including approximately **\$300–380/month baseline AWS infrastructure** and a planning budget of approximately **\$400/month**, while separating usage-dependent services from predictable infrastructure costs.
- Worked with **Kubernetes operational tooling including kubectl /K9s, Helm, and Prometheus**, including deploying/upgrading monitoring charts, Kubernetes service discovery configuration, NodePort exposure, and Helm release management.
- Developed understanding and operational practices around **white-box vs. black-box monitoring and OpenTelemetry**, alongside application and infrastructure observability.
- Supported production-readiness activities including infrastructure validation, deployment coordination, code-freeze communication, release planning, troubleshooting, documentation, and collaboration with frontend/backend engineering teams.

Shorter version for your actual resume

The version above is useful as your **master experience list**, but I would not put all of it on a resume. For a 1–2 page resume, I would use something closer to this:

DevOps Engineer | AcordAI

- Designed and managed **multi-environment AWS infrastructure using Terraform**, including VPC, ECS Fargate, ECR, ALB, RDS PostgreSQL, ElastiCache Redis, S3, IAM, Secrets Manager, Route 53, ACM, Amplify, and CloudWatch.
- Built automated **CI/CD pipelines with GitHub Actions**, integrating AWS OIDC, Docker/ECR builds, ECS deployments, frontend deployments, branch protection, PR validation, and controlled production releases.
- Designed secure AWS networking using **public/private/database subnets, NAT Gateway, security groups, private RDS, and SSM-based bastion access** without exposing databases publicly.
- Built production-ready **RDS PostgreSQL Multi-AZ** infrastructure with encryption, automated backups, PITR, Secrets Manager credentials, TLS enforcement, deletion protection, monitoring, and failover planning.
- Deployed and operated containerized applications on **ECS Fargate behind an ALB**, configuring HTTPS, health checks, routing, sticky sessions, resource allocation, logging,

and deployment strategies.

- Implemented DevSecOps controls including **Gitleaks secret scanning, pre-commit checks, IAM least-privilege practices, AWS Secrets Manager, TLS, encryption at rest, and GitHub protected branches**.
- Managed **Route 53, ACM and Amplify** for application hosting and custom domains, including migration of production DNS from GoDaddy while preserving Microsoft 365 mail records.
- Troubleshoot application and infrastructure performance using **CloudWatch, ECS events/metrics, ALB metrics, RDS monitoring, AWS CLI and browser network analysis**, resolving deployment, IAM, routing, secret injection, database, and HTTP upload issues.
- Designed a scalable asynchronous workload architecture using **Amazon SQS and ECS workers** to decouple long-running document/policy processing from synchronous API workloads.
- Integrated AWS services including **Amazon Textract and ElastiCache Redis**, managing application permissions, encryption, networking, and infrastructure configuration.
- Performed **AWS cost optimization and production capacity planning**, evaluating Fargate, NAT, ALB, RDS, Redis, CloudWatch and networking costs while balancing development savings with production HA requirements.
- Worked with **Docker, Kubernetes, Helm, K9s, Prometheus and OpenTelemetry concepts** for container orchestration and observability, while maintaining engineering runbooks and supporting production releases.

Skills this experience supports

AWS: ECS Fargate, ECR, RDS PostgreSQL, VPC, ALB, S3, IAM, Route 53, ACM, Amplify, Secrets Manager, CloudWatch, ElastiCache, Textract, SQS, Systems Manager

DevOps/IaC: Terraform, GitHub Actions, CI/CD, Infrastructure as Code, Git, GitHub OIDC, Docker, Gitleaks

Containers & Observability: ECS, Docker, Kubernetes, Helm, K9s, Prometheus, CloudWatch, OpenTelemetry

Networking & Security: VPC, DNS, HTTPS/TLS, SSL certificates, IAM, security groups, NAT Gateway, private subnets, secret management, encryption, Multi-AZ architecture

This is already enough material to position the role as **hands-on AWS DevOps/Cloud Engineer experience**, rather than simply “AWS administration.” The strongest part is that you’ve worked across the lifecycle: **design → Terraform → CI/CD → deployment → security → monitoring → troubleshooting → production HA → cost optimization**.

Yes. **16 bullets is too many for one role** on a resume. It makes the strongest work harder to notice.

For AcordAI, I'd target **7–9 strong bullets** and combine related activities. Something like this is much sharper:

DevOps Engineer | AcordAI

- **Designed and managed AWS infrastructure across Development and Production**, using Terraform to provision VPC, ECS Fargate, ALB, RDS PostgreSQL, ElastiCache, ECR, S3, IAM, Route 53, ACM, Secrets Manager and CloudWatch.
- **Built end-to-end CI/CD pipelines using GitHub Actions**, automating validation, Docker builds, ECR publishing, ECS deployments and AWS Amplify frontend releases, with secure AWS authentication through **GitHub OIDC**.
- **Designed highly available and secure production architecture** with Multi-AZ PostgreSQL, private subnets, load balancing, automated backups, PITR, TLS, encryption, Secrets Manager and IAM least-privilege controls.
- **Owned containerized application deployments on ECS Fargate**, configuring task definitions, ALB routing, health checks, resource allocation, logging, sticky sessions and production release workflows.
- **Strengthened DevSecOps practices** through Gitleaks secret scanning, pre-commit security checks, protected branches, PR validation and controlled dev → main production releases.
- **Troubleshoot infrastructure and application performance** using CloudWatch, ECS events, ALB metrics, RDS monitoring and application logs, identifying deployment, networking, database and concurrency bottlenecks.
- **Designed an asynchronous SQS + ECS worker architecture** to decouple long-running document-processing workloads from the API and improve application scalability.
- **Managed DNS, SSL and application hosting** using Route 53, ACM and AWS Amplify, including production domain migration planning while preserving Microsoft 365 email DNS records.
- **Performed AWS cost optimization and production capacity planning**, evaluating Fargate, NAT Gateway, ALB, RDS, Redis and monitoring costs while balancing cost, security and high availability.

Tech Stack: AWS, Terraform, GitHub Actions, Docker, ECS Fargate, Kubernetes, Helm, PostgreSQL, Redis, Prometheus, CloudWatch, Git, Linux

This is much better for a resume because a recruiter can understand in **20–30 seconds** that you've worked with **AWS + Terraform + CI/CD + containers + production + security + monitoring**.

If this is your **current/main DevOps role**, I'd use **8–9 bullets**. For older roles, I'd reduce them to **4–6 bullets each**.
